RESULT SUMMARY

Best Model Selected

- **Selected Model**: Artificial Neural Network (ANN).
- **Selection Logic**: Identified as superior due to its continuous mathematical manifold and physical consistency with fluid thermodynamics compared to jagged, tree-based alternatives.

Final Performance Metrics (R^2 Scores)

The models were evaluated on a held-back test set comprising 20% of the 2,700 total samples.

- **XGBoost**: 0.9854.
- **Random Forest**: 0.9785.
- **Artificial Neural Network (ANN)**: 0.9234.
- **Support Vector Regression (SVR)**: 0.8711.

Sample Predictions vs. Actual Values

- **High-Purity**: Models demonstrated high accuracy at the (1.0, 1.0) mark on parity plots, effectively mastering the steady-state plateau.
- **Error Distribution**: ANN exhibited a Gaussian (bell-shaped) error profile, while XGBoost showed a spiky density at zero with unpredictable outliers.
- **Residual Consistency**: The ANN maintained tight clustering to the 45-degree physics line across most operational ranges.

Important Observations

- **Data Density**: 1,698 out of 2,700 data rows yielded a purity of exactly 1.0, representing a dominant physical regime in the 30-stage configuration.
- **MIMO Capability**: The ANN successfully learned the latent interconnected physics between product purity (x_D) and reboiler energy duty (Q_R).
- **Computational Efficiency**: Surrogate implementation reduced prediction times from seconds to milliseconds without sacrificing thermodynamic precision.
- **Safety Margin**: ANN errors were found to be normally distributed, providing a predictable safety margin for advanced process control (APC).
